AYUDANTÍA NO PRESENCIAL

1) MODELOS COMBINADOS

Cargar librerias

```
#install.packages("MASS")
#install.packages("randomForest")
#install.packages("ggplot2")
#install.packages("tibble")
#install.packages("dplyr")
#install.packages("ipred")
set.seed(125)
library(MASS)
library(randomForest)
library(ggplot2)
library(tibble)
library(dplyr)
library(ipred)
```

Cargar set de datos

Separamos en train y test.

NOTA: Dado que las etapas de preprocesamiento y transformacion no son el foco seran omitidas

```
data("Boston")
index <- sample(nrow(Boston),nrow(Boston)*0.70) # separar train/test
boston.train <- Boston[index,]
boston.test <- Boston[-index,]
rm(Boston)
```

Exploración del set

El data set tiene 14 columnas: 1 variables respuesta y 13 predictores.

```
head(Boston)
```

Bagging

En lugar de ajustar un único árbol, se ajustan muchos de ellos en paralelo formando un "bosque". En cada nueva predicción, todos los árboles que forman el "bosque" participan aportando su predicción. Como valor final, se toma la media de todas las predicciones (variables continuas) o la clase más frecuente (variables cualitativas). Uno de los métodos de bagging más conocidos es Random Forest. El paquete de R "ipred", tiene funciones facilitadoras para el Bagging.

Instalamos el paquete ipred

```
#install.packages("ipred")
library(ipred)
```

Bagging para un arbol de decisiones

Modelo simple de Bagging con 100 replicaciones. Calculamos el error cuadrático medio.

```
boston.bag<- bagging(medv~., data = boston.train, nbagg=100)
boston.bag.pred<- predict(boston.bag, newdata = boston.test)
```

```r
mean((boston.test$medv-boston.bag.pred)^2)
rm(boston.bag,boston.bag.pred)
```

14.6008387807017

Para el caso de un árbol normal.

```r
#install.packages("rpart")
library(rpart)
```

```r
boston.tree<- rpart(medv~., data = boston.train)
boston.tree.pred<- predict(boston.tree, newdata = boston.test)
mean((boston.test$medv-boston.tree.pred)^2)
rm(boston.tree,boston.tree.pred)
```

21.1008575041993

Como podemos ver, ingresar árboles paralelos al modelo disminuye el error. Cabe preguntarse, **¿Hasta cuantos árboles es eficiente ingresar?**

Numero optimo de arboles

```r
ntree<- c(1, 3, 5, seq(10, 200, 10))
MSE.test<- rep(0, length(ntree))
for(i in 1:length(ntree)){
  boston.bag1<- bagging(medv~., data = boston.train, nbagg=ntree[i])
  boston.bag.pred1<- predict(boston.bag1, newdata = boston.test)
  MSE.test[i]<- mean((boston.test$medv-boston.bag.pred1)^2)
}
plot(ntree, MSE.test, type = 'l', col=2, lwd=2)
rm(boston.bag1,boston.bag.pred1)
```

> **Notar que a mayor cantidad de árboles llega un punto donde su ganancia marginal es nula. Además, ingresar demasiados árboles tiende a sobreajustarse a la base de entrenamiento, lo que perjudicaría el modelo y su capacidad de adaptarse a nuevos datos.**

Out-of-bag (OOB)

OOB es una forma de validar un modelo de Random Forest. En cada iteración de Bootstrap, las muestras no usadas servirán para testear el modelo. Finalmente, se muestra el MSE disminuído.

```r
boston.bag.oob<- bagging(medv~., data = boston.train, coob=T, nbagg=100)
boston.bag.oob # coob=T significa que sea TRUE el uso de OOB
rm(boston.bag.oob)
```

```
Bagging regression trees with 100 bootstrap replications

Call: bagging.data.frame(formula = medv ~ ., data = boston.train, coob = T,
    nbagg = 100)

Out-of-bag estimate of root mean squared error:  4.2551
```

RANDOM FOREST

Random Forest es un derivado del Bagging, y mejora significativamente la predicción. La idea es que, aleatoriamente, se selecciona un subconjunto de predictores como variables candidatas en cada separación

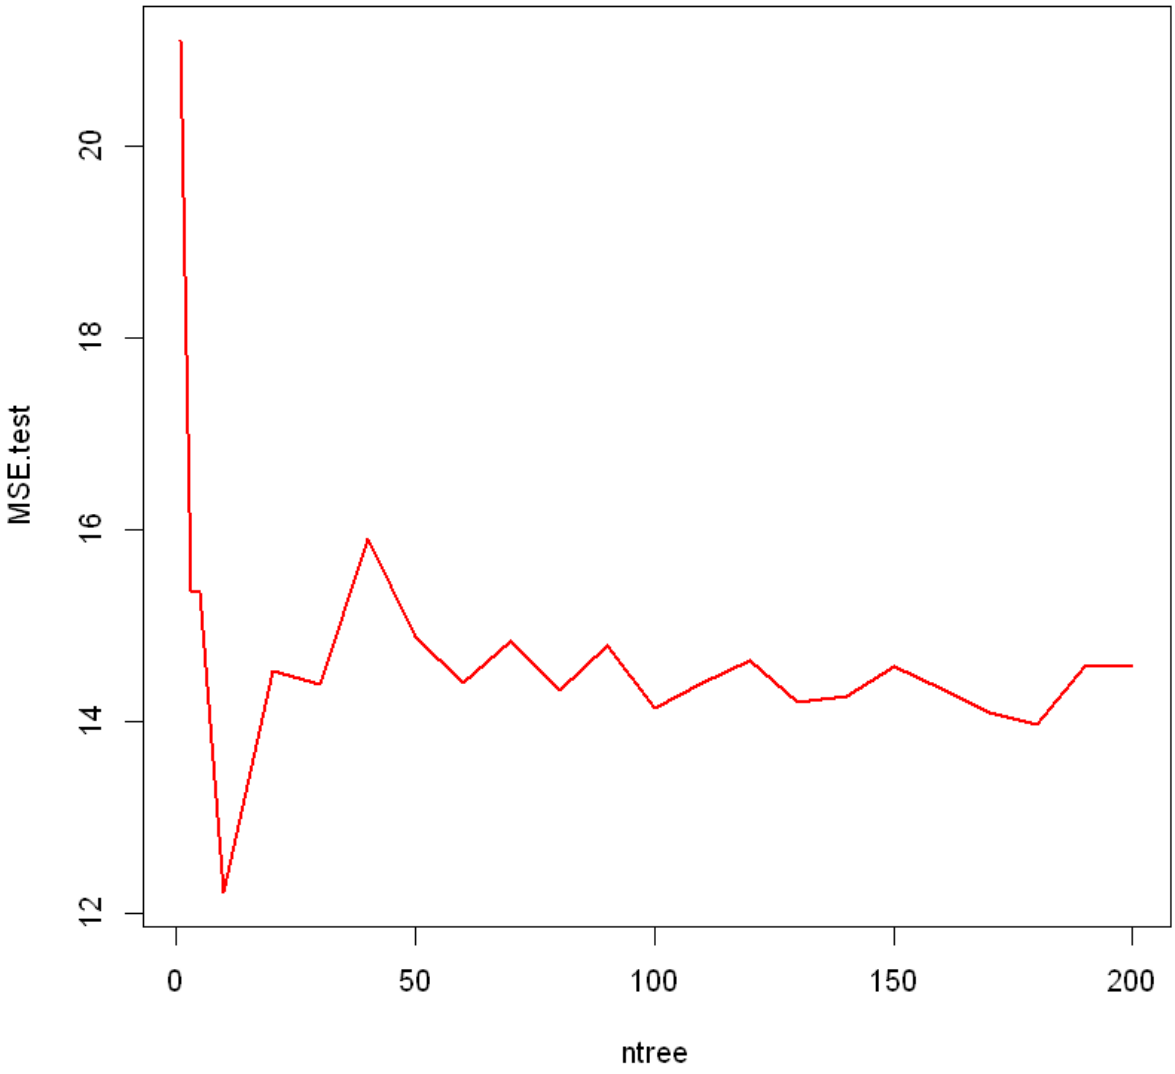

Figure 1: png

del árbol. La razón de esto es adaptarse a las correlaciónes naturales entre las variables y los árboles, así se reduce la varianza al agregar árboles.

```
library(randomForest)
boston.rf<- randomForest(medv~., data = boston.train, importance=TRUE)
boston.rf
```

```
Call:
 randomForest(formula = medv ~ ., data = boston.train, importance = TRUE)
               Type of random forest: regression
                     Number of trees: 500
No. of variables tried at each split: 4

          Mean of squared residuals: 12.50255
                    % Var explained: 85.06
```

Por defecto, el modelo de árbol de regresión utiliza un tercio de las variables como predictoras en cada iteración. Mientras que utiliza la raíz de las variables para las el problema de clasificación poor defecto. En ambos casos se puede cambiar modificando el hyperparámetro **mtry=**. También se puede especificar el número de árboles con el hyperparámetro **ntree=**. por defecto se utilizan 500. El argumento **importance=TRUE** nos permite ver la importancia de cada variable en el modelo.

Tabla con Feature Importances

```
tabla<- rownames_to_column(data.frame(boston.rf$importance),"Variable")
tabla
```

Como se dijo previamente, el número de variables candidatas en cada iteración o separación es la raíz de las variables totales: Si son 13 variables, m~4. También podemos especificar este número en el argumento **mtry=**. Ahora podemos graficar las diferencias del error en OOB y el testing y como éstos cambian según el hyperparametro **mtry=**

```
oob.err<- rep(0, 13)
test.err<- rep(0, 13)
for(i in 1:13){
  fit<- randomForest(medv~., data = boston.train, mtry=i)
  oob.err[i]<- fit$mse[500]
  test.err[i]<- mean((boston.test$medv-predict(fit, boston.test))^2)
  cat(i, " ")
}
matplot(cbind(test.err, oob.err), pch=15, col = c("red", "blue"), type = "b", ylab = "MSE", xlab = "mtry
  legend("topright", legend = c("test Error", "OOB Error"), pch = 15, col = c("red", "blue"))

BOOSTING

Consiste en ajustar secuencialmente múltiples modelos sencillos, llamados weak learners, de forma que cada modelo aprende de los errores del anterior. Como valor final, al igual que en bagging, se toma la media de todas las predicciones (variables continuas) o la clase más frecuente (variables cualitativas). Tres de los métodos de boosting más empleados son AdaBoost, Gradient Boosting y * Stochastic Gradient Boosting*.

Notar que debemos especificar el tipo de distribución en distribution = **"gaussian"** al trabajar en árboles de regresión. Por defecto esto trabaja en distribución **Bernoulli** para clasificación binaria.

- **n.trees** corresponde al número de árboles a ajustar. A mayor n.trees podría haber mayor sobreajuste.
- **shrinkage** es un argumento para decidir cuanta contribución aporta cada nuevo árbol al modelo.
- **interaction.depth** es cuantas separaciones tendrá cada árbol.

La mejor manera de ajustar estos parámetros es mediante Validación cruzada y grid search (que se verá en la respectiva ayudantía).

```
ntree<- seq(100, 10000, 100)
predmat<- predict(boston.boost, newdata = boston.test, n.trees = ntree)
err<- apply((predmat-boston.test$medv)^2, 2, mean)
plot(ntree, err, type = 'l', col=2, lwd=2, xlab = "n.trees", ylab = "Test MSE")
abline(h=min(test.err), lty=2)
```

2) GRID SEARCH

El paquete caret R proporciona un Gridsearch donde puede especificar los parámetros para tratar su problema. Y probará todas las combinaciones y localizará la combinación que ofrezca los mejores resultados. No todos los algoritmos de aprendizaje automático están disponibles para el ajuste En https://topepo.github.io/caret/available-models.html pueden verificar que parametros del modelo de caret se pueden ajustar

R

Primera opción de Grid Search: Automatic Grid

Permite que el sistema lo haga automáticamente. Esto se puede hacer configurando **tuneLength** para indicar el número de valores diferentes para probar para cada parámetro del algoritmo.

OJO: ESTE MÉTODO PUEDE TOMAR ARTO TIEMPO COMPUTACIONAL Y EN ESPECIAL CUANDO ELIGEN UN **tunelength** MUY GRANDE

MODELO SVM

El modelo **svmPoly** tiene como parametros: degree, scale, C

C: es el parámetro de regularización, C, del término de error es el grado de la función del núcleo polinomial ('poli') y es ignorado por todos los demás núcleos. El valor predeterminado es 3.

- El código en la celda a continuación utiliza la capacidad del paquete R Caret para estimar los mejores hiperparámetros usando la validación cruzada 5 veces. Esta primera validación cruzada se realiza utilizando ROC como la métrica. Hay algunos puntos a tener en cuenta aquí:
- **trainControl** se utiliza para definir el entrenamiento. Por ejemplo:
  - `method = cv` corresponde a la cross-validation y `number=10` corresponde a 10 fold.
  - Se especifica la función `twoClassSummary`, lo que convierte a ROC en la métrica para la optimización de hiperparámetros.
  - El argumento `tuneLength` le dice al algoritmo que pruebe diferentes valores predeterminados para el parámetro principal

```
control_svm <- trainControl(method='cv',
                        number=10,

                        verboseIter = TRUE,
                        summaryFunction = twoClassSummary,
                        classProbs = TRUE)
# Entrenamiento de la base training utilizando el metodo de support vector machine con AUTOMATIC GRID
model_SVM_AG <- train(
  Class ~ ., training,
  method = "svmPoly",
  trControl = control_svm,
  tuneLength = 6,
  metric ="ROC"
  )
```

ROC was used to select the optimal model using the largest value.
The final values used for the model were degree = 3, scale = 0.01 and C = 2.
```

La mejor configuración del modelo con automatic grid es **degree = 3, scale = 0.01 and C = 2**

```

Como podemos notar el modelo con automatic grid tiene una mejor performance

MODELO DECISSION TREE

- A diferencia del modelo SVM ahora compararemos dos modelos DT, uno sin GridSearch y uno con GridSearch
- Parametros del DT C50 son trials, model, winnow

Primero definimos los fold y las repeticiones del crossvalidation Usaremos el método **repeatedcv** que es un cross validation repetido segun la cantidad de **repeats** ingresadas.

```
Control_DT_c50 <- trainControl(method = "repeatedcv",
                           number = 10,
                           repeats = 3,verboseIter = TRUE,

Podemos notar que el modelo con automitcgrid tiene una mejor performance

Segunda opción es Grid Search: Manual Grid

- La segunda forma de buscar parámetros de algoritmo es especificar una grilla de sintonización manualmente.
- En la grilla cada parámetro del algoritmo se puede especificar como un vector de posibles valores.
- Estos vectores se combinan para definir todas las combinaciones posibles para probar.

```
#primero definimos los fold y las repeticiones del crossvalidation
Control_DT_c50 <- trainControl(method = "repeatedcv",
                               number = 10,
                               repeats = 3,verboseIter = FALSE,
                              summaryFunction = twoClassSummary,
                               classProbs = TRUE)
#Segundo definimos la grilla mediante vectores

grid_DT <- expand.grid( .winnow = c(TRUE,FALSE), .trials=c(7,15,17,18,20), .model="tree" )

model_DT_2 <- train(
  Class ~ ., training,
  tuneGrid=grid_DT,
  method = "C5.0",
    metric ="ROC",
  trControl = Control_DT_c50)
```

```

```
   TRUE   20      0.7466128  0.7261905  0.6674603

Tuning parameter 'model' was held constant at a value of tree
ROC was used to select the optimal model using the largest value.
The final values used for the model were trials = 17, model = tree and winnow
 = FALSE.
```

El método de munualGrid obtiene mejores resultados que el modelo normal, pero requiere de ir probando valores para ir acotando el resultado

RANDOM FOREST

El siguiente Random Forest tiene 2 hiperparámetros para configurar: - mtry: Número de variables muestreadas al azar como candidatos en cada división. - ntree: Número de árboles para crecer que viene definido por default en 500

Cargamos la libreria para el modelo

```
#install.packages("randomForest")
library(randomForest)
```

```
#Definimos la configuración de entrenamiento como un cross validation 10 fold con 3 repeticiones
control_rf <- trainControl(method="repeatedcv", number=10, repeats=3, summaryFunction = twoClassSummary
                           classProbs = TRUE)
# definimos los valores para mtry seran del 1 al 20
grid_rf <- expand.grid(.mtry=c(1:20))
rf <- train(Class~., data=training, method="rf", metric="ROC", tuneGrid=grid_rf, trControl=control_rf)
print(rf)
plot(rf)
```

```

```
dotplot(results)
```

Podemos notar que el mejor resultado ROC lo tiene el **ntree = 500**

Ahora a partir de **ntree =500** buscamos el óptimo para **mtry**

```
rf_list$`500`$bestTune
```

A data.frame: 1 × 1
